

UX Improvement Proposals — Azisly.ai

Objective

The purpose of these improvements is to enhance user engagement quality while reducing interaction friction across key preparation flows within the platform.

The proposals focus on:

- making practice interactions more actionable
- improving visibility and decision confidence
- increasing lightweight engagement opportunities
- maintaining consistency with the existing product experience

The goal is not to introduce heavy workflows, but to improve clarity and feedback loops within already existing user journeys.

1. Lightweight Voice-Based Answer Practice Evaluation

Existing Flow

Within the interview preparation section, users receive AI-generated personalized answers for possible interview questions based on their desired role.

Users are encouraged to:

- practice answers aloud
- rehearse responses before interviews

However, the current experience lacks any immediate feedback mechanism to help users understand whether repeated practice is improving their delivery.

This creates a gap between:

- passive answer consumption
and
 - active answer improvement.
-

Problem Statement

Currently:

- users can read and rehearse answers
- but cannot quickly validate whether their spoken delivery is improving

As a result:

- practice becomes directionless
- users may disengage after reading
- there is no measurable reinforcement loop
- the platform misses an opportunity for lightweight quality engagement

While the platform already includes a full AI interviewer experience (“Mock Mate”), that workflow is comparatively heavier and designed for end-to-end interview simulation.

Users may not always want:

- a full mock interview
- time commitment
- role-wide evaluation
- contextual pressure

They may simply want to:

- practice one question repeatedly
 - test clarity/confidence quickly
 - iterate on delivery in isolation
-

Proposed Solution

Introduce a lightweight “Test Answer in Voice” interaction directly inside the AI-generated Q&A accordion experience.

Suggested Flow

1. User expands a question accordion.
2. User reads AI-generated personalized answer.
3. User clicks:
 - “Test in Voice”
4. User records spoken response.
5. System performs lightweight analysis.
6. User receives quick-result feedback.

The interaction should remain:

- minimal
- fast
- non-intimidating
- embedded within the existing UI

This should not feel like a separate assessment module.

Proposed Metrics

The evaluation should intentionally remain lightweight.

Purpose:

- directional feedback
- not full interview scoring

Suggested metrics:

1. Accuracy

Measures:

- alignment with expected answer structure/content
- whether major answer points were covered

Purpose:

- gives user a rough signal of answer relevance/completeness

2. Pauses

Measures:

- excessive silence
- hesitation frequency
- delivery interruptions

Purpose:

- gives user awareness about fluency and confidence
-

Why Lightweight Metrics Instead of Full Analysis

The intention is:

- low friction
- fast retry loops
- repeated practice encouragement

Heavy scoring systems can:

- increase anxiety
- slow interaction
- overlap excessively with Mock Mate

This feature should complement Mock Mate, not replace it.

Mock Mate remains:

- the comprehensive interview simulation layer

This feature becomes:

- the rapid practice layer
-

UX Considerations

The UI should:

- consume minimal space

- integrate naturally into existing accordion layout
- avoid visual clutter

Suggested interaction style:

- compact CTA button
- inline metric chips/cards
- minimalistic result state

The feature should feel:

- assistive
- lightweight
- iterative

rather than evaluative or intimidating.

Long-Term Product Value

These metrics can later contribute toward:

- engagement quality indicators
- practice consistency tracking
- personalized improvement trends
- adaptive coaching systems

This creates future opportunities for:

- progress visualization
- personalized recommendations
- engagement intelligence

without requiring immediate complexity in V1.

2. Resume Template Visibility Improvements — Resume Architect

Existing Flow

Within Resume Architect, users select resume templates during the resume tailoring process.

Currently:

- templates are displayed in card-slider format
 - preview image appears above
 - textual details appear below
-

Problem Statement

The current presentation introduces decision friction because:

- template previews appear visually small
- users must focus harder to understand layout differences
- comparison confidence is reduced
- visual scanning becomes inefficient

As a result:

- template selection feels less intuitive
- users may make uncertain choices
- visual exploration becomes cognitively heavier than necessary

The issue is not lack of templates.

The issue is:

- insufficient visual clarity during comparison.
-

Proposed Improvements

1. Change Card Orientation

Current orientation:

- vertical

Proposed orientation:

- horizontal

Suggested structure:

- larger preview image on left
- supporting information on right

Benefits:

- larger visible template area
 - easier layout recognition
 - improved scan efficiency
 - stronger visual differentiation between templates
-

2. Zoom-on-Hover Interaction

Introduce subtle zoom interaction on hover.

Purpose:

- improve inspection without navigation
- create richer interaction feedback
- enhance visual confidence

Important:

- zoom should remain subtle
 - avoid aggressive motion or excessive scaling
-

3. Dedicated Preview Option

Allow users to open larger template preview on click.

Possible approaches:

- modal preview
- side drawer preview
- expanded focused view

Purpose:

- reduce uncertainty before selection
 - improve template evaluation confidence
 - minimize repetitive back-and-forth selection behavior
-

UX Philosophy Behind These Improvements

Resume templates are highly visual decisions.

Users should not need to:

- mentally reconstruct layouts from small previews
- zoom with effort
- repeatedly focus to understand differences

The platform should optimize for:

- quick visual recognition
- confident comparison
- reduced cognitive strain

The proposed improvements aim to make template exploration:

- more immersive
- more intuitive
- more decision-friendly

without increasing UI complexity aggressively.

Overall Product Impact

These improvements collectively aim to:

- reduce interaction friction
- improve confidence during user decisions
- encourage active participation
- create faster feedback loops
- increase meaningful engagement quality

Importantly, both proposals maintain alignment with the platform's current product direction:

- AI-assisted preparation
- low-friction coaching
- guided improvement experiences
- lightweight but intelligent interactions

The objective is not feature expansion for its own sake, but refinement of existing preparation workflows to make them more effective and user-friendly.
